

Why do we need a working designer's tool for the event-driven world — from classical to quantum? And, what is it? (May 4, 2026)

In two earlier posts, I asked two related questions:

1 What is the lens design behind a physical-AI system that perceives the world by change?

And:

2 How should lens design adapt when we move from classical imaging to quantum/event-driven imaging?

The answers are not trivial.

Here, I have now consolidated this perspective as a document:

✦ From Strehl to Kullback–Leibler:

■ A Unified Fidelity Framework for Stationary, Event-Driven, and Quantum Imaging Optics

(version 11)

The full technical document needs time to read.

So I also prepared a visualization deck for optical engineers who want to quickly see the main idea, the 2×2 fidelity map, and the practical design consequences.

The key message is:

✦ Strehl is not wrong — but once the detector protocol changes, the lens-design merit function must also change.

■ Technical document on GitHub: <https://lnkd.in/gPUyjVYd>

■ Check repositories - From-Strehl-to-Kullback-Leibler

✦ The visualization deck is attached below for a quick view.
